```

La fonction qui sera utilisée pour les prétraitements: MyCleanText

- Mettre le texte en minuscule
- Se débarrasser des stopwords
- Se débarrasser des nombres
- Stemmatisation
- Lemmatisation ..

La fonction MyshowAllScores prend le y_test et le y_predict, affiche l'accuracy et le classification report avec la matrice de confusion.

```
#.....Fonction
MyCleanText .....
.....

2      MIXTURE/OTHER
3      TRUE/FALSE
4      TRUE/FALSE
      ...
2523   TRUE/FALSE
2524   TRUE/FALSE
2525   TRUE/FALSE
2526   TRUE/FALSE
2527   TRUE/FALSE
Name: regrouped, Length: 2528, dtype: object

```

la taille de Xt est (2528,)

```

y EST 0          TRUE/FALSE
1      MIXTURE/OTHER
2      MIXTURE/OTHER
3      TRUE/FALSE
4      TRUE/FALSE
...
2523   TRUE/FALSE
2524   TRUE/FALSE
2525   TRUE/FALSE
2526   TRUE/FALSE
2527   TRUE/FALSE
Name: regrouped, Length: 2528, dtype: object

```

Les valeurs de true et false sont:

```

true/false      1578
mixture/other    950
Name: regrouped, dtype: int64

```

Le jeu de données étant déséquilibré, on a pensé à appliquer le downsampling pour équilibrer nos données. on sélectionne des lignes aléatoirement de TRUE/FALSE de telle sorte que le nombre de lignes de TRUE/FALSE soit = au nbr de lignes de MIXTURE/OTHER. et on mélange le DataFrame

#On applique du sous-échantillonnage (downsampling) : car on a plus de FALSE (578) que des TRUE (211)

Séparer les classes en deux dataframes

```

df_false_true = dftrain[dftrain['regrouped'] == 'TRUE/FALSE']
df_other_mixture = dftrain [dftrain['regrouped'] == 'MIXTURE/OTHER']

```

Sous-échantillonner la classe majoritaire (FALSE) pour obtenir un nombre égal d'échantillons pour chaque classe

```

df_subsampled = df_false_true.sample(n=len(df_other_mixture),
random_state=42)

```

Concaténer les deux dataframes

```

dftrain = pd.concat([df_subsampled, df_other_mixture])

```

Mélanger aléatoirement les données

```

dftrain = dftrain.sample(frac=1, random_state=42)

```

```

X_text=dftrain.iloc[0:,1:2]
X_title=dftrain.iloc[0:,2:3]

```

```

print("le texte est")

Etape 2 : Classification selon la colonne TITRE

Tests de Classification pour trouver le meilleur classifieur, les meilleurs paramètres de prétraitement et les meilleurs hyperparamètres.

Avant de classifier on applique les entités nommées, Cette fonction utilise Spacy pour extraire les entités nommées à partir d'une liste de textes et les stocke dans une liste pour être affichées avec leurs labels correspondants.

```

nlp = spacy.load("en_core_web_sm")
texte=dftrain['title']
#Créer une liste pour stocker les entités nommées
entities = []
# Traiter chaque texte individuellement et ajouter les entités à la liste
for phrase in texte:
    phrase_str = str(phrase) # Convertir l'élément en chaîne de caractères
    doc = nlp(phrase_str)
    for ent in doc.ents:
        entities.append((ent.text, ent.label_))

# Afficher les entités nommées
for entity in entities:
    print(entity[0], entity[1])

```

Le flux de sortie a été tronqué et ne contient que les 5000 dernières lignes.

Cette fonction a pour but d'ajouter le type d'entité de chaque token détecté à coté de chaque entité détectée dans le texte qu'elle prend en entrée, et retourne le texte modifié avec les informations ajoutées sur les entités nommées.

```
def add_entity_name(text):  
    if text is None or pd.isna(text):  
        return ""  
  
    doc = nlp(text)  
    # Créer une liste pour stocker les nouveaux tokens  
    nouveaux_tokens = []  
  
    # Parcourir les tokens et ajouter des informations selon le type  
    d'entité  
    for token in doc:  
        if token.ent_type_:  
            # Ajouter le nom de l'entité (type d'entité) à côté de  
            l'entité  
            nouveaux_tokens.append(f"{token.text}  
( {token.ent_type_} )")  
        else:  
            nouveaux_tokens.append(token.text)  
  
    # Reconstruire le texte avec les informations ajoutées  
    nouveau_texte = " ".join(nouveaux_tokens)  
    return nouveau_texte
```

```

Ici, c'est une étape importante, on va tester différents classifieurs, pour chacun des classifieurs, on va appliquer le prétraitement + Vectorisation TfIdf, et on applique une cross_val_score avec un Kfold de 10 fois, par la suite on stocke dans une liste all_results la moyenne des accuracy + l'écart type et on la trie par ordre décroissant de moyenne d'accuracy et d'écart type. on remarque que les 2 meilleurs sont SVM et RF qu'on va sélectionner pour leur appliquer le GridSearch sur les paramètres des prétraitements + leurs hyperparamètres pour pouvoir choisir le meilleur.

```

On a un pipeline pour chaque prétraitement différent, on essaye pas mal (miniscule, lemmatisation, miniscule + lemmatisation..) et on stocke le fit_transform de nos X_train, X_test sur les pipelines dans des listes qui vont contenir tous les fit_transform des pipelines pour chaque classifieur, par la suite on parcourt ces listes là, on itère dessus, et chaque élément de la liste (train) va passer par le GridSearch et puis on prédit sur son correspondant dans liste (test).

```

Ici, c'est une étape importante, on va tester différents classifieurs, pour chacun des classifieurs, on va appliquer le prétraitement + Vectorisation TfIdf, et on applique une cross_val_score avec un Kfold de 10 fois, par la suite on stocke dans une liste all_results la moyenne des accuracy + l'écart type et on la trie par ordre décroissant de moyenne d'accuracy et d'écart type. on remarque que les 2 meilleurs sont SVM et RF qu'on va sélectionner pour leur appliquer le GridSearch sur les paramètres des prétraitements + leurs hyperparamètres pour pouvoir choisir le meilleur.

```

Comparaison des algorithmes

On a un pipeline pour chaque prétraitement différent, on essaye pas mal (miniscule, lemmatisation, miniscule + lemmatisation..) et on stocke le fit_transform de nos X_train, X_test sur les pipelines dans des listes qui vont contenir tous les fit_transform des pipelines pour chaque classifieur, par la suite on parcourt ces listes là, on itère dessus, et chaque élément de la liste (train) va passer par le GridSearch et puis on prédit sur son correspondant dans la liste (test).

Etape 4 : Classification selon la colonne Text_title (concaténation de la colonne text et la colonne title) :

On concatène les deux colonnes text et titre de notre DataFrame dftrain

```
text_title = dftrain.apply(lambda x : '{ }'.format(x['text'],x['title']),axis=1)
dftrain['text_title'] = text_title
X_text_title = dftrain.iloc[0:,-1]
X_text_title.reset_index(drop = True, inplace = True)
```

Ici, Pas besoin d'appliquer les entités entité dans cette étape vu qu'on les a appliqué sur les colonnes texte et titre et ici on les concatènes donc on les a automatiquement

On scinde notre jeu de données en jeu d'apprentissage et jeu de test

```
X=dftrain['text_title']
X_train,X_test,y_train,y_test=train_test_split(X,y,test_size =
0.2,random_state=8)
print("X_train is \n",X_train.shape)
print("y_train is \n",y_train.shape)
print("X_test is \n",X_test.shape)
print("y_test is \n",y_test.shape)
```

Ici, c'est une étape importante, on va tester différents classifieurs, pour chacun des classifieurs, on va appliquer le prétraitement + Vectorisation TfIdf, et on applique une cross_val_score avec un Kfold de 10 fois, par la suite on stocke dans une liste all_results la moyenne des accuracy + l'écart type et on la trie par ordre décroissant de moyenne d'accuracy et d'écart type. on remarque que les 2 meilleurs sont SVM et RF qu'on va sélectionner pour leur appliquer le GridSearch sur les paramètres des prétraitements + leurs hyperparamètres pour pouvoir choisir le meilleur

```
score = 'accuracy'
seed = 7
allresults = []
results = []
names = []
```

```

Comparaison des algorithmes

On a un pipeline pour chaque prétraitement différent, on essaye pas mal (miniscule, lemmatisation, miniscule + lemmatisation..) et on stocke le fit_transform de nos X_train, X_test sur les pipelines dans des listes qui vont contenir tous les fit_transform des pipelines pour chaque classifieur, par la suite on parcourt ces listes là, on itère dessus, et chaque élément de la liste (train) va passer par le GridSearch et puis on prédit sur son correspondant dans la liste (test).

```
np.random.seed(42) # Set the random seed for NumPy
```

```
#X_test = np.ravel(X_test)

##Seconde classification: Other vs mixture

On crée un nouveau dataframe avec que les lignes contenant dans la colonne rating les valeurs other et mixture

```
dftrain = dftrainbase.loc[dftrainbase['rating'].isin(['other',
'mixture'])]
print(dftrain.shape)
print(dftrainbase.columns)
y = dftrain.iloc[:, -2]
print("les valeurs de OTHER et MIXTURE maintenant sont ",
y.value_counts())

(950, 5)
Index(['id', 'text', 'title', 'rating', 'regrouped'], dtype='object')
les valeurs de OTHER et MIXTURE maintenant sont  mixture    716
other        234
Name: rating, dtype: int64
```

Le jeu de données étant déséquilibré, on a pensé à appliquer le downsampling pour équilibrer nos données. on sélectionne des lignes aléatoirement de TRUE/FALSE de telle sorte que le nombre de lignes de TRUE/FALSE soit = au nbr de lignes de Other. et on mélange le DataFrame

```
# Compter le nombre d'observations dans chaque catégorie
mixture_count = dftrain['rating'].value_counts()['mixture']
other_count = dftrain['rating'].value_counts()['other']
```

```

# Trouver le nombre minimum d'observations parmi les catégories
min_count = min( mixture_count, other_count)

# Sous-échantillonner les catégories pour équilibrer les quantités
mixture_sampled = dftrain[dftrain['rating'] ==
'mixture'].sample(min_count, random_state=42)
other_sampled = dftrain[dftrain['rating'] ==
'other'].sample(min_count, random_state=42)

# Concaténer les échantillons pour obtenir un nouveau dataframe
équilibré
dftrain = pd.concat([mixture_sampled,other_sampled])

# Mélanger aléatoirement les données
dftrain = dftrain.sample(frac=1, random_state=42)
print(dftrain)
X_text=dftrain["text"]
X_title=dftrain["title"]
y=dftrain.iloc[0:,-2]
print("\n")
print("la taille de y_train est " ,y.shape)
print("\n")
print("les valeurs de OTHER et MIXTURE maintenant sont
" ,y.value_counts())

On a un pipeline pour chaque prétraitement différent, on essaye pas mal (miniscule, lemmatisation, miniscule + lemmatisation..) et on stocke le fit_transform de nos X_train, X_test sur les pipelines dans des listes qui vont contenir tous les fit_transform des pipelines pour chaque classifieur, par la suite on parcourt ces listes là, on itère dessus, et chaque élément de la liste (train) va passer par le GridSearch et puis on prédit sur son correspondant dans la liste (test).

```

Ici, c'est une étape importante, on va tester différents classifieurs, pour chacun des classifieurs, on va appliquer le prétraitement + Vectorisation Tfidf, et on applique une cross_val_score avec un Kfold de 10 fois, par la suite on stocke dans une liste all_results la moyenne des accuracy + l'écart type et on la trie par ordre décroissant de moyenne d'accuracy et d'écart type. on remarque que les 2 meilleurs sont SVM et RF qu'on va sélectionner pour leur appliquer le GridSearch sur les paramètres des prétraitements + leurs hyperparamètres pour pouvoir choisir le meilleur.

```

```

Comparaison des algorithmes

On a un pipeline pour chaque prétraitement différent, on essaye pas mal (miniscule, lemmatisation, miniscule + lemmatisation..) et on stocke le fit_transform de nos X_train, X_test sur les pipelines dans des listes qui vont contenir tous les fit_transform des pipelines pour chaque classifieur, par la suite on parcourt ces listes là, on itère dessus, et chaque élément de la liste (train) va passer par le GridSearch et puis on prédit sur son correspondant dans la liste (test).
